Running title: NEC and TGF-β
Sources of Funding: Supported by the NIH awards HD059142, HD043397, American Gastroenterological Association 2006 Research Scholar Award, and a research grant from the CACA Jones Family Foundation (A.M.), NIH grants HD046513, HL092906, ATS PH-06-006 (N.A.), and ES015323 (M.A.). Blood monocytes and adult jejunal tissue were received from Core 2 of the UAB Mucosal Immunology and HIV Center (DK64400). The work was made possible in part by the Research Facilities Improvement Grant C06RR15490 from the National Center for Research Resources.
ABSTRACT:

**Background & Aims:** Premature neonates are predisposed to necrotizing enterocolitis (NEC), an idiopathic, inflammatory bowel necrosis. We investigated the hypothesis that NEC occurs in the preterm intestine due to incomplete ‘non-inflammatory’ differentiation of intestinal macrophages, which increases the risk of a severe mucosal inflammatory response to bacterial products.

**Methods:** We compared inflammatory properties of human/murine fetal, neonatal, and adult intestinal macrophages. To investigate gut-specific macrophage differentiation, we next treated monocyte-derived macrophages with conditioned media from ex planted human fetal and adult intestinal tissues. Transforming growth factor-beta (TGF-β) expression and bioactivity were measured in fetal/adult intestine and in NEC. Finally, we used wild-type and transgenic mice to investigate the effects of deficient TGF-β signaling on NEC-like inflammatory mucosal injury.

**Results:** Intestinal macrophages in the human preterm intestine (fetus/premature neonate), but not in full-term neonates and adults, expressed inflammatory cytokines. Macrophage cytokine production was suppressed in the developing intestine by TGF-β, particularly the TGF-β₂ isoform. NEC was associated with decreased tissue expression of TGF-β₂ and decreased TGF-β bioactivity. In mice, disruption of TGF-β signaling worsened NEC-like inflammatory mucosal injury, whereas enterally supplementation with recombinant TGF-β₂ was protective.

**Conclusions:** Intestinal macrophages progressively acquire a non-inflammatory profile during gestational development. TGF-β, particularly the TGF-β₂ isoform, suppresses macrophage inflammatory responses in the developing intestine and protects against inflammatory mucosal injury. Enterally-administered TGF-β₂ protected mice from experimental NEC-like injury.

**Key words:** necrotizing enterocolitis, macrophage, newborn, inflammation, TGF-β
Introduction:

Premature neonates born before 32 weeks of gestation or with a birth weight <1500 grams are predisposed to necrotizing enterocolitis (NEC), an idiopathic, inflammatory bowel necrosis characterized by *pneumatosis intestinalis* (accumulation of gaseous products of bacterial fermentation within the bowel wall), inflammation, and tissue necrosis.¹² Existing data indicate that bacterial flora normally present in the gut lumen, not specific bacterial pathogens, play a major role in the pathogenesis of NEC.¹² The pathophysiological importance of bacteria in NEC is underscored by the frequent detection of bacteria and *pneumatosis* in intestinal tissue, occurrence of NEC only after postnatal bacterial colonization and never in the sterile intrauterine microenvironment prior to birth, inability to induce NEC-like lesions in germ-free experimental animals, and by observations that enteral antibiotics may reduce the incidence of NEC in preterm infants.²³ Based on current evidence, NEC is believed to occur when mucosal injury or altered permeability in the preterm intestine permits the translocation of luminal bacteria across the epithelial barrier, which, in turn, triggers a severe inflammatory response.²⁴

Gut mucosal injury and bacterial translocation are frequent events in critically-ill patients of all ages, but unlike in premature infants, these invading bacteria do not evoke a NEC-like inflammatory response in the mature intestinal mucosa. Bacteria that breach the gut epithelial barrier are normally eliminated by resident macrophages in the *lamina propria*, the first phagocytic cells of the innate immune system to encounter these microorganisms.⁵⁶ Unlike macrophages in other organ systems that release cytokines/chemokines upon phagocytosis of bacteria to stimulate a local inflammatory response, intestinal macrophages are profoundly suppressed for cytokine production.⁶ This unique dichotomy of phagocytic versus inflammatory properties in intestinal macrophages plays an important role in maintaining the normal absence
of inflammation in the gut mucosa (despite close proximity to immunostimulatory bacteria), as illustrated by spontaneous onset of enterocolitis in genetically-modified mice with defects in differentiation of intestinal macrophages. In this context, we hypothesized that the risk of NEC in the premature intestine is related to the state of differentiation of intestinal macrophages. We postulated that the non-inflammatory differentiation of intestinal macrophages is a function of gestational maturation and is therefore, incomplete in the preterm intestine, increasing the risk of a severe mucosal inflammatory response to bacterial products. In this study, we investigate maturational changes in gut macrophage differentiation in the context of NEC using a variety of in-vitro and in-vivo models.
Methods:

Human intestinal tissue samples: Human intestinal tissues were collected after approval by local Institutional Review Boards. Fetal intestinal tissue (11-24 wks, n=25) was obtained at elective terminations of pregnancy. Tissue samples of advanced NEC (n=8) were compared with healthy tissue margins obtained during resection for indications other than NEC (premature neonates: repair of ostomy, n=5; gestational age 27, 27.5, 28.5, 30.5, and 32 wks; full-term neonates: atresia/obstruction; n=3). Adult tissues were obtained during bariatric surgery (n=5).

Immunohistochemistry: Tissue sections (and cells) were stained for macrophage markers (HAM56 or F4/80), tumor necrosis factor (TNF)-α, interleukin (IL)-8, TGF-β2, and TGF-β receptors using our previously-described fluorescence protocol6, 10-12 (included in online supplement).

Murine intestinal macrophages: Murine studies were approved by the local Institutional Animal Care and Use Committee. Murine intestinal macrophages were isolated by standard methods including density centrifugation and adherence to polystyrene8, 13 described in the online supplement.

Real-time polymerase chain reaction (PCR): Inflammatory cytokines and TGF-β isoforms were measured by our previously-described quantitative PCR method using SYBR green.14-15

Tissue-conditioned media (T-CMs): We prepared T-CMs from fresh human and murine intestinal tissue by using a previously-reported protocol16. Briefly, fresh intestinal tissue was cleaned, IECs were removed by dispase/ethylenediaminetetraacetic acid to expose the lamina

6
propria, and the remaining tissue was incubated overnight in serum-free RPMI. The exfoliated epithelial cells were incubated overnight in a separate plate to prepare epithelial-conditioned media (E-CMs). In some experiments, we used intact tissue (with epithelium) to prepare the T-CMs. A detailed protocol is included in the online supplement.

Treatment of monocyte-derived macrophages with T-CMs: Blood monocytes from healthy adult volunteers were isolated by Ficoll-Hypaque centrifugation and immunoselection with CD14 microbeads (Miltenyi). Monocyte-derived macrophages (20,000/well) were incubated in 96-well plates with T-CM (250, 500, and 1000 µg total protein/mL) x 2-24 hrs and then stimulated with 500 ng/mL *E. coli* LPS (pre-determined optimum; Sigma) for up to 18 hrs.

Measurement of inflammatory cytokines: TNF-α (human and murine), IL-6, IL-1β, and IL-8 were measured by commercially-available ELISA kits (R&D, Minneapolis, MN).

Neutrophil chemotaxis: Culture supernatants from monocyte-derived macrophages were tested for neutrophil chemotactic activity using our fluorescence-based protocol described in the online supplement.

NF-κB activation: Macrophages were treated with T-CMs and LPS as above. NF-κB p65 phosphorylation was measured by ELISA (SuperArray Biosciences).

TGF-bioactivity: TGF-β bioactivity was measured by a quantitative luciferase assay; T-CMs were added for 16 hrs to mink lung epithelial cells transfected with a luciferase plasmid containing the TGF-β-responsive promoter of the platelet activator inhibitor-1 (PAI-1) gene;
Smad2/3 phosphorylation (ser423, ser425) was measured by western blots using polyclonal antibodies against total and phosphorylated smad 2 (Santa Cruz) and appropriate secondary reagents. TGF-β activity was neutralized in vitro by addition of excess (15 or 50 µg/mL) neutralizing anti-human TGF-β antibody.

**Assays for TGF-β isoforms:** Total and active TGF-β₁, TGF-β₂, and TGF-β₃ were measured by ELISA (R&D). T-CMs containing only one unique TGF-β isoform were derived from 20-24 wk T-CMs (n=3) by removing two of the three TGF-β isoforms by immunoprecipitation; the presence/absence of TGF-β isoforms was confirmed by ELISA. Macrophages were treated with parent or derivative T-CM prior to LPS stimulation. In some experiments, we treated macrophages with 15.6-2000 pg/mL recombinant human TGF-β₁, TGF-β₂, and TGF-β₃ (R&D) instead of T-CMs before stimulation with LPS.

**Mice:** DNIIR mice were treated with zinc sulfate (50 µg/gm/day subcutaneous; pre-determined optimum dose) for up to 7 days. Identification of DNIIR mice and measurement of DNIIR mRNA is described in the online supplement. To confirm the loss of TGF-β-mediated signaling upon zinc supplementation, we administered recombinant TGF-β₂ (100 ng, intra-peritoneal) in DNIIR mice (after 0, 3, and 7 days of zinc supplementation) and measured smad phosphorylation in intestinal tissue after 1 hour.

Gut mucosal injury was induced in 10-12 day old mouse pups by intraperitoneal administration of PAF (50 µg/kg) and LPS (1 mg/kg). Mice were sacrificed 2 hrs after PAF and LPS administration and mucosal injury was graded on a 5-point scale: grade 0: no injury; grade 1: mild separation of lamina propria; grade 2: moderate separation of submucosa; grade 3: severe separation and/or edema in submucosa; grade 4: transmural injury. To investigate
whether enterally-administered TGF-β2 protected against mucosal injury, we treated some mice with 100 ng recombinant TGF-β2 2 hours prior to PAF and LPS administration. The protective effect of TGF-β2 were confirmed in a second experimental model of NEC where 10-day-old mouse pups were separated from the dam, provided formula feedings every 3 hours and exposed to hypoxia (5% oxygen for 2 min) twice daily prior to feedings. The formula was prepared by mixing 15gm of Similac 60/40 (Abbott Laboratories, Abbott Park, IL) in 75 ml of Esbilac canine milk replacer (PetAg, Hampshire, IL); 200 µL/5 gm body weight by gavage over 2-3 min. Pups were sacrificed after 4 days and intestinal injury was measured as above.

Statistical analysis: Statistical analyses were performed using the software package SigmaStat version 5.1 (Systat, San Jose, CA) as described in figure legends.
Results:

Macrophages in the preterm human intestine express inflammatory cytokines: To investigate our hypothesis that the inflammatory downregulation of intestinal macrophages is a function of gestational maturation, we first compared macrophages in intestinal tissue samples from human fetuses, premature and full-term neonates, and adults by Immunohistochemistry for inflammatory cytokines. Consistent with existing information,6,25 macrophages in the full-term neonatal and adult intestine did not express TNF-α or IL-8/CXCL8. However, macrophages in preterm intestine (from fetuses and premature neonates) showed strong immunoreactivity for TNF-α (Fig. 1A) and IL-8 (not depicted).

Macrophages isolated from the murine fetal intestine express TNF-α upon LPS stimulation in vitro but become tolerant to LPS upon exposure to media conditioned with adult intestinal tissue: We next investigated developmental changes in the inflammatory properties of intestinal macrophages in vitro. Because primary human fetal intestinal macrophages were not available (limited availability of fresh human fetal tissue), we compared murine CD11b+ F4/80+ CD11cint intestinal macrophages isolated from fetal, neonatal, and adult mouse intestine as a model system.8 In support of our immunohistochemical data from the human intestine, murine intestinal macrophages from embryonic day 15 (E15) and E18 fetuses, but not from newborn pups or adults, produced TNF-α following LPS stimulation in vitro (Fig. 1B).

We have shown previously that intestinal macrophages are derived from ‘pro-inflammatory’ blood monocytes, which differentiate under the influence of the extracellular matrix (ECM) in the lamina propria to acquire a ‘non-inflammatory’ profile.5,10 To explain the
intact inflammatory responses of fetal intestinal macrophages, we hypothesized that tissue factor(s) that suppress the inflammatory responses of macrophage precursors in the intestine are expressed as a function of gestational maturation, and are therefore, deficient in the fetus. To test this possibility, we treated E15 intestinal macrophages (exposed in vivo to an immature matrix) and ‘supplied’ the differentiating factor(s) missing from the fetal intestine by adding media conditioned with ex planted adult mouse jejunum. In support of our hypothesis, adult T-CMs suppressed fetal intestinal macrophages for LPS-induced TNF-α production (inset).

Human peripheral blood monocyte-derived macrophages develop LPS-tolerance upon exposure to media conditioned with human adult, but not fetal, intestinal tissue: The inflammatory downregulation of intestinal macrophages can be recapitulated in vitro by exposing monocyte-derived macrophages to media conditioned with ex planted adult intestinal tissue. To investigate whether the non-inflammatory differentiation of intestinal macrophages undergoes a similar ‘maturation’ in human and murine fetal intestine, we treated monocyte-derived macrophages with T-CMs prepared from fetal tissue of various gestational ages. Consistent with our hypothesis, we found that the suppressive effect of fetal T-CMs on LPS-induced macrophages cytokine production increased with gestational age but remained significantly less than that of adult T-CM (Fig. 2A; supporting data from a real-time PCR array shown in Supplementary fig. 1). T-CM suppression of macrophage cytokine production followed a similar pattern when macrophages were stimulated with heat-killed Listeria monocytogenes (to stimulate toll-like receptor-2) instead of LPS (not depicted).

The maturational increase in T-CM suppression of macrophage cytokine production was not affected by variations in the protocol for T-CM preparation, such as the presence or absence of IECs on ex planted intestinal tissue. A similar (albeit weaker) maturational pattern was
detected when culture supernatants from exfoliated IECs were added to macrophage cultures instead of T-CMs (Supplementary fig. 2). Finally, as T-CMs from premature and full-term neonatal tissue were not available, we used tissue lysates of frozen intestinal tissue samples from 20-24 wk fetuses, term neonates, and adults in some experiments. These lysates were less efficacious than T-CMs but showed a similar maturational increase in the suppression of LPS-induced TNF-α production (not depicted).

Media conditioned with human intestinal tissue induce LPS-tolerance in human peripheral blood monocyte-derived macrophages by providing TGF-β: To understand the inflammatory downregulation of intestinal macrophages, we evaluated TGF-β-, IL-10-, and programmed death-1-ligand 1 (PD1L1)-mediated effects as possible mechanisms. TGF-β was the most plausible mediator of these effects because the inflammatory downregulation of intestinal macrophages can be reproduced by exposing macrophages to ECM products present in T-CMs, and preformed TGF-β, but not IL-10 and PD1L1, is stored in intestinal ECM. Consistent with the maturational increase in T-CM suppression of macrophage cytokine production, we detected increasing TGF-β bioactivity in these T-CMs (Fig. 3A). Similarly, T-CM treatment of macrophages induced the phosphorylation of smad2 (a signaling event specifically associated with TGF-β), which became progressively more robust with increasing gestational age of the intestinal tissue sample (Fig. 3B). The role of TGF-β in T-CM suppression of macrophage cytokine production was confirmed by the reversal of T-CM effects upon neutralization of TGF-β (Fig. 3C).

Media conditioned with human intestinal tissue suppress cytokine production in human monocyte-derived macrophages primarily via the TGF-β2 isoform: The expression of TGF-β2, but not TGF-β1 or TGF-β3, increased in intestinal tissue with maturation (Fig. 4A-C).
ascertain the relative contribution of the three TGF-β isoforms to the anti-inflammatory effects of T-CMs, we removed two of three isoforms in different aliquots of T-CMs by immunoprecipitation. T-CM derivatives containing TGF-β₂ were most effective in suppressing LPS-induced cytokine production (Fig. 4D). TGF-β₁ had a smaller effect, whereas TGF-β₃ did not affect macrophage cytokine production. These effects were blocked by neutralizing isoform-specific antibodies (R&D, not depicted). In support of these data, we found that recombinant human TGF-β₂ was more potent than recombinant TGF-β₁ or recombinant TGF-β₃ in suppressing macrophage cytokine production (inset).

TGF-β₂ expression is decreased in intestinal tissues samples resected from patients with NEC: Based on our findings, we argued that macrophages in preterm intestine, which are yet to undergo inflammatory downregulation, should predispose all premature infants to inflammatory mucosal injury. In this context, the actual 5-15% incidence of NEC in premature infants appeared to be surprisingly low. To investigate whether clinically-evident NEC occurs in infants with the lowest levels of TGF-β₂ expression, we compared tissue expression of TGF-β₂ in NEC (n=8; mean gestational age ± standard error = 28±1.5 wks) versus intestinal conditions other than NEC (n=5; 29.1±2 wks) and normal midgestation fetal intestine (n=6; 22±0.4 wks). TGF-β₂ expression and TGF-β bioactivity were lower in NEC than in the controls (Fig. 4). The concentrations of TGF-β₁ were also lower in NEC (not depicted), while TGF-β₃ was expressed near the lower limit of detection.

TGF-β protects mouse pups against NEC-like intestinal injury: We next used a murine model to investigate whether decreased TGF-β-mediated signaling could worsen inflammatory mucosal injury. Although TGF-β₂ was the most potent of the three TGF-β isoforms in suppressing macrophage cytokine production, TGF-β₁ and TGF-β₃ showed similar effects at
high concentrations (Fig. 4D). In the intestine, TGF-β is normally stored in a bound-form in the lamina propria, where these peptides are anchored to ECM proteins. Depending on the physical proximity to a differentiating macrophage, these matrix stores of TGF-β could theoretically provide biologically-relevant local concentrations of TGF-β1 and/or TGF-β3 in the immediate microenvironment of the macrophage. Based on these considerations, we could not exclude the possibility of some redundancy in the anti-inflammatory effects of TGF-β isoforms and therefore, opted against the use of isoform-specific deletion/neutralization models. We used a transgenic mouse that can be induced to lose TGF-β receptor II (TGF-β RII) expression and consequently, all TGF-β-mediated signaling. In these DNIIR mice, which express a kinase-defective TGF-β RII transgene upon zinc supplementation, we were able to induce a partial deficiency of TGF-β effects after 3 days of zinc supplementation and a complete abrogation of all TGF-β signaling after 7 days (supplementary Fig. 3). To determine whether TGF-β protects the neonatal intestine against inflammatory injury, we induced gut mucosal injury by intraperitoneal administered PAF and LPS in wild-type, 3-day-zinc DNIIR, and 7-day-zinc DNIIR mice (n=18 per group). The severity of intestinal injury worsened with increasing loss of TGF-β effects in the intestine (Fig. 6A).

We next investigated whether enterally-administered recombinant TGF-β2 could protect against inflammatory mucosal injury in mouse pups. The enteral route was chosen because (1) TGF-β2 is normally expressed in human milk in high concentrations\(^{26-27}\) and (2) TGF-β receptors (TGF-β RI, TGF-β RII, and TGF-β RIII) are widely-expressed in human fetal as well as murine intestine (Supplementary fig. 4). Administration of recombinant TGF-β2 (100 ng; dose calculated to provide 10 times the amount of TGF-β2 received by a rodent pup in one day)\(^{28}\) by gavage 2 hours prior to PAF and LPS administration protected these pups against mucosal injury (Fig. 6B). We then confirmed the protective effects of TGF-β2 in another experimental
model of NEC, where formula-fed 10-day-old mouse pups exposed to hypoxia and hypothermia
develop intestinal injury. Similar to the results in our PAF-LPS model, daily administration of
TGF-β2 (100 ng; one single dose in morning for 4 days) was protective against mucosal injury in
this model (Fig. 6C). In addition to the reduced severity of intestinal injury, we also noted a
reduction in the frequency of injury (9 control pups with intestinal injury versus 1 pup with injury
in TGF-β2–treated group, \( p<0.05 \))
We present a detailed investigation into the normal development of LPS-tolerance in intestinal macrophages and a novel pathophysiological model for NEC with possible therapeutic implications. In contrast to the ‘non-inflammatory’ functional profile of intestinal macrophages seen in the mature host, we show that macrophages in the preterm intestine can respond to bacterial products to produce a robust inflammatory response. In the normal fetus, intestinal macrophages undergo progressive inflammatory downregulation and resemble macrophages in the adult intestine by term gestation. However, in the event of a midgestation delivery, when the inflammatory downregulation of the resident macrophages is still incomplete, ‘premature’ bacterial colonization of the intestinal mucosa may predispose these infants to inflammatory mucosal injury as seen during NEC (Fig. 7).

The progressive suppression of inflammatory responses of intestinal macrophages we observed during gestational development mirrors a similar maturational reduction in the expression of inflammatory cytokines in the gut epithelium, indicating that these changes may be a part of a larger, more generalized change in the inflammatory milieu in the intestine. Because IECs are a major source of TGF-β₂, these cells may conceivably play a regulatory role in the differentiation of macrophage precursors in the intestine. Interestingly, intestinal macrophages become tolerant to bacterial products in utero as part of an intrinsic, developmentally-regulated program, which contrasts with the development of LPS-tolerance in alveolar macrophages in the postnatal period following exposure to bacterial flora. Although TGF-β₂ is widely expressed in the lung, these developmental differences between intestinal vs. alveolar macrophages could be related to the absence of TGF-β₂ expression in the distal airspaces and alveoli where most macrophages are normally located.
Immunomodulatory effects of TGF-β₂ have been previously reported in diverse conditions such as in systemic inflammatory response syndrome, traumatic brain injury, and atopy. While TGF-β₂ shares the Smad signaling pathways with the other isoforms of TGF-β, the absence of the arg-gly-asp (RGD) integrin-binding motif in TGF-β₂ indicates that activation/stabilization mechanisms other than those related to integrin αvβ6 may assume greater importance in TGF-β₂–mediated signaling. TGF-β₂ usually requires betaglycan (TGF-β receptor III) as a co-receptor for efficient binding to TGF-β receptors I and II, although emerging evidence indicates that certain splice variants of TGF-β R II may bind TGF-β₂ in the absence of betaglycan. Phenotypic differences between mice lacking individual TGF-β isoforms emphasize the existence of hitherto unknown differences in the intracellular signals activated by these isoforms.

We report for the first time that TGF-β₂ expression and TGF-β bioactivity is decreased in NEC. TGF-β₂ expression was decreased in NEC to levels even lower than the premature/fetal intestine, suggesting that genetic/epigenetic variability in TGF-β₂ expression may increase the risk of NEC in a premature neonate. The low levels of TGF-β we observed in NEC are unique to NEC and are not due to consumption during mucosal inflammation; TGF-β expression is increased in mucosal inflammatory states such as ulcerative colitis and Crohn’s disease. Whereas TGF-β effects have not been investigated in NEC, the protective effect of TGF-β in our model is consistent with previous reports where TGF-β₁ protected against experimental colitis induced in mice by rectal administration of trinitrobenzene sulfonic acid or by adoptive transfer of Th1 cells.

Several studies have now shown that cytokines and growth factors present in amniotic fluid and human milk can survive digestion in the stomach and the proximal small intestine by
binding to cognate receptors on the epithelium, due to deficiency of digestive enzymes during early neonatal period, or because of an intrinsic resistance to gastric and enteral proteases in many cytokines due to the presence of specific structural motifs that render these peptides resistant to digestion. The neonatal intestinal epithelium can absorb intact proteins and other macromolecules, indicating that enterally-administered cytokines such as TGF-β2 may be bioavailable in the mucosa. TGF-β2 is expressed in high concentrations in amniotic fluid and human milk and is therefore, normally ingested by the fetus and newborn infant in large amounts. In contrast, the absence of TGF-β2 in infant formula calls for speculation that the protective effect of breast milk against NEC (as compared to formula) may be, at least partially, due to TGF-β2 (Fig. 7). Since recombinant TGF-β2 can be easily synthesized in large amounts, our findings justify aggressive evaluation of the safety and efficacy of enterally-administered TGF-β2 as a prophylactic strategy against NEC.

FIGURE LEGENDS:

Fig.1. (A) Macrophages in the preterm human intestine express TNF-α. Photomicrographs of jejunum (magnification 100x) show the distribution of immunoreactivity for the macrophage marker HAM56 (red) and TNF-α (green). Co-localization is shown in a computer-merged image (yellow). Macrophages in preterm (26-wk premature infant) but not in the full-term intestine show strong immunoreactivity for TNF-α. Inset: high-magnification images (400x) of selected area highlight TNF-α expression in HAM56⁺ macrophages in the preterm intestine. (B) Macrophages isolated from the murine fetal intestine express TNF-α upon LPS stimulation in vitro: Bar diagram shows TNF-α concentration (means ± SEM) in culture supernatants from primary murine intestinal macrophages. Macrophages from the E15 and E18 murine fetuses, but not those from the P1 pups or adult mice, show LPS-induced TNF-α expression. Photomicrographs above the bar diagram show co-localization of F4/80 (a murine macrophage marker) and TNF-α in the fetal, but not in adult murine intestinal macrophages. Inset: bar diagram shows that tissue-conditioned media prepared from the adult mouse intestine suppressed LPS-induced TNF-α production in E15 murine fetal intestinal macrophages. Experiments represent 3 T-CMs per group; replicates were averaged. * indicates p<0.05 in Kruskall-Wallis H test.
Fig. 2. Human peripheral blood monocyte-derived macrophages develop LPS-tolerance upon exposure to media conditioned with human adult, but not fetal, intestinal tissue (A).

Bar diagrams show TNF-α, IL-6, IL-1β, and IL-8 concentrations (means ± SEM) in culture supernatants from monocyte-derived macrophages treated with T-CMs. Fetal T-CMs became more effective in suppressing macrophage cytokine production with gestational maturation but remained inferior to adult T-CMs. Data representative of 3 independent experiments, each performed with tissues from 3-5 fetuses per fetal group and 3 adults. (B) T-CM suppression of macrophage cytokine production shown in panel A correlated with a corresponding reduction in the neutrophil chemotactic activity of these culture supernatants. Bar diagram (means ± SEM) show the number of neutrophils migrating across a polycarbonate filter in a microchemotaxis chamber towards culture supernatants from experiments in panel A. Data are representative of 3 independent experiments, each performed with 3-5 supernatants from each group; (C) Unlike T-CMs prepared from adult intestinal tissue, fetal T-CMs did not block LPS-induced NF-κB activation in macrophages. Bar diagram (means ± SEM) shows ratio of phosphorylated: total NF-κB p65. Data represent 3-4 T-CMs per group. All experimental groups in the 3 panels were compared by Kruskall-Wallis H-test.
Fig. 3. Media conditioned with human intestinal tissue induce LPS-tolerance in human peripheral blood monocyte-derived macrophages by providing TGF-β: (A) TGF-β bioactivity, measured as activation of the platelet activator inhibitor-1 promoter in a luciferase assay, increases in intestinal tissue-conditioned media with maturation. Data represent n = 3-5 samples per group; (B) T-CM activation of smad signaling in human monocyte-derived macrophages increases with maturation. Bar diagram shows densitometric analysis of blots (means ± SEM). Data are representative of 3 independent experiments, each performed with a distinct set of T-CMs and utilized 2 different monocyte donors; (C) T-CM suppression of LPS-induced cytokine production in human monocyte-derived macrophages was reversed by neutralization of TGF-β in the conditioned media. Bar diagram shows LPS-induced TNF-α (means ± SEM) production in macrophages. Data represent n = 4-6 T-CMs per group. All experimental groups in the 3 panels were compared by Kruskall-Wallis H-test.
Fig. 4. Media conditioned with human intestinal tissue suppress cytokine production in human monocyte-derived macrophages primarily via the TGF-β_2 isoform: (A) mRNA expression of TGF-β_2, but not of TGF-β_1 or TGF-β_3, increases with intestinal maturation. Data depicted as fold-change above 10-14 wk fetal intestine (means ± SEM) and represent n = 3-4 per group; (B) TGF-β_2 immunoreactivity (green) increases in the intestine with gestational maturation. TGF-β_2 was detected in epithelium and in cells in the lamina propria. Nuclear staining (blue) was obtained with DAPI. (C) Concentrations of active and total TGF-β_2 increased in T-CMs with maturation. Bar diagrams show means ± SEM. Data represent n=3-5 per group; (D) TGF-β_2 is the most important TGF-β isoform in T-CM downregulation of macrophage cytokine production. We removed two of the three TGF-β isoforms by immunoprecipitation in separate T-CM aliquots to obtain T-CM derivatives containing only one of the three TGF-β isoforms. Bar diagram (means ± SEM) shows that T-CMs containing TGF-β_2 were most effective in suppressing LPS-induced TNF-α production in macrophages. Data are representative of 3 independent experiments, each performed with T-CMs derived from 3-4 subjects in each group; Inset: recombinant TGF-β_2 is the most potent of the three isoforms in suppressing LPS-induced TNF-α production in macrophages. Data are representative of 3 independent experiments. All experimental groups in the 3 panels were compared by Kruskall-Wallis H-test.
Fig. 5. TGF-β₂ expression is decreased in intestinal tissues samples resected from patients with NEC: TGF-β₂ expression in tissue samples of NEC (n=8) was lower than in the mid-gestation fetal (n=6) and preterm neonatal intestine (n=5). Data show measurements by ELISA (means ± SEM). Insets show TGF-β₂ mRNA expression (top left) and TGF-β bioactivity (top right). Groups were compared by Kruskall-Wallis H-test.

Fig. 6. TGF-β protects mouse pups against NEC-like intestinal injury: (A) Loss of TGF-β signaling in mice worsened NEC-like intestinal injury induced by intraperitoneal administration of PAF and LPS. Bar diagram (means ± SEM) shows the severity of mucosal injury on a 5-point scale in wild type mice, transgenic DNIIR mice with a partial deficiency of TGF-β signaling (3 days of zinc supplementation) and DNIIR mice with complete disruption of TGF-β signaling (7 days of zinc supplementation); n =18 mice per group. Injury scores in DNIIR mice treated with zinc for 3 or 7 days but not treated with PAF and LPS were similar to WT controls (0.24 ±0.11 and 0.26±0.20, respectively; not depicted in the bar diagram). Groups were compared by Kruskall-Wallis H-test. (B) Enteral administration of TGF-β₂ prior to PAF and LPS administration in mouse pups reduced the severity of NEC-like intestinal injury; n =18 mice per group, comparison by Mann-Whitney U-test. (C) Enteral administration of TGF-β₂ once a day in formula-fed mouse pups reduced the severity of intestinal injury induced by hypoxic stress; n =18 mice per group, comparison by Mann-Whitney U-test.
Fig. 7. Incomplete development of macrophage tolerance to bacterial products predisposes the preterm intestine to NEC. In the mature intestine (schematic representation on the left), epithelial and stromal cell-derived TGF-β attenuates the inflammatory responses of intestinal macrophages to luminal bacteria or their products. In contrast, in the premature infant (right), the inflammatory responses of intestinal macrophages remain intact because TGF-β expression, and therefore, mucosal tolerance to bacterial products, are deficient. Bacterial products trigger an intense inflammatory reaction, causing widespread tissue damage. Enteral supplementation of recombinant TGF-β₂ is a potential therapeutic strategy to prevent NEC in neonates.

A) PRO-INFLAMMATORY CYTOKINES

B) NEUTROPHIL CHEMOTAXIS

C) NF-κB ACTIVATION

- TNF-α (ng/mL)
- IL-6 (ng/mL)
- IL-1β (ng/mL)
- IL-8 (ng/mL)

Number of migrating neutrophils (x 10^3)

Ratio of phospho: total NF-κB p65

Comparison of cytokine levels and neutrophil chemotaxis across different time points and treatments.

Significance levels indicated for each comparison.

**A. Intestinal Injury Induced by Intraperitoneal PAF and LPS**

- Wild type mice
- Wild type mice treated with PAF + LPS
- DNIIR mice after 3-day Zn supplementation, treated with PAF + LPS
- DNIIR mice after 7-day Zn supplementation, treated with PAF + LPS

**B. Mucosal Injury Score**

- PAF + LPS
- Enteral TGF-β₂, then treated with PAF + LPS

**C. Experimental NEC**

- Experimental NEC in control animals
- Experimental NEC in animals receiving supplemental TGF-β₂
Pro-inflammatory cytokines and chemokines, Toll-like receptor and other inflammatory signals.

Mature Host
- Luminal bacteria
- Stromal cells
- Resident macrophages
- TGF-β
- Epithelial cells
- Mucosal injury
- Pro-inflammatory cytokine and chemokine production
- Normal, regulated inflammatory response

Premature Infant
- Luminal bacteria
- Stromal cells
- Resident macrophages
- Pro-inflammatory cytokine and chemokine production
- Deficient TGF-β activity
- Excessive, dysregulated inflammatory response

Enteral TGF-β₂ as a potential therapeutic tool.
