ABSTRACT Endothelial nitric oxide synthase (eNOS)–mediated NO production plays a critical role in the regulation of vascular function and pathophysiology. Caveolin-1 (Cav-1) binding to eNOS holds eNOS in an inactive conformation; however, the mechanism of Cav-1–mediated inhibition of activated eNOS is unclear. Here the role of Src-dependent Cav-1 phosphorylation in eNOS negative feedback regulation is investigated. Using fluorescence resonance energy transfer (FRET) and coimmunoprecipitation analyses, we observed increased interaction between eNOS and Cav-1 following stimulation of endothelial cells with thrombin, vascular endothelial growth factor, and Ca2+ ionophore A23187, which is corroborated in isolated perfused mouse lung. The eNOS/Cav-1 interaction is blocked by eNOS inhibitor l-NAME, nitroarginine methyl ester (hydrochloride) and Src kinase inhibitor 4-amino-5-(4-chlorophenyl)-7-(t-butyl) pyrazolo[3, 4-d] pyrimidine. We also observe increased binding of phosphomimicking Y14D-Cav-1 mutant transduced in human embryonic kidney cells overexpressing eNOS and reduced Ca2+-induced NO production compared to cells expressing the phosphodefective Y14F-Cav-1 mutant. Finally, Src FRET biosensor, eNOS small interfering RNA, and NO donor studies demonstrate NO-induced Src activation and Cav-1 phosphorylation at Tyr-14, resulting in increased eNOS/Cav-1 interaction and inhibition of eNOS activity. Taken together, these data suggest that activation of eNOS promotes Src-dependent Cav-1–Tyr-14 phosphorylation and eNOS/Cav-1 binding, that is, eNOS feedback inhibition.

INTRODUCTION Production of nitric oxide (NO) by endothelial cell nitric oxide synthase (eNOS; NOS3) regulates vascular tone, blood flow, leukocyte-endothelial interactions, platelet adhesion and aggregation, and vascular smooth muscle cell proliferation (Sessa, 2004; Atochin and Huang, 2010). Studies demonstrated direct interaction of eNOS with caveolin-1 (Cav-1; Feron et al., 1996; García-Cardeña et al., 1996) and that Cav-1 functions as an endogenous negative regulator of eNOS activity (Drab et al., 2001; Razani et al., 2001; Zhao et al., 2002; Wunderlich et al., 2006; Maniatis et al., 2008). Specifically, eNOS binds to the caveolin scaffold domain (CSD; amino acids 82–101; García-Cardeña et al., 1997; Bucci et al., 2000), and alanine scanning of the CSD identified Thr-90 and -91 and Phe-92 as...
These mechanisms predict that eNOS binding to Cav-1 leads to eNOS inactivation (Oess et al., 2006; Wang et al., 2009). Both of these mechanisms lead to eNOS inhibition. However, the molecular mechanisms responsible for restoring eNOS enzymatic activity to its basal state and whether its binding to Cav-1 is important in this process have not been established. In the present study, we tested the hypothesis that in endothelial cells, there is an intrinsic NO-dependent mechanism of eNOS negative feedback regulation dependent on phospho–Cav-1 binding.

**RESULTS**

**Kinetics of interaction between eNOS and Cav-1**

To assess spatial and temporal eNOS and Cav-1 binding, CHO cells were transfected with fluorescent protein conjugates, and stimulation-dependent fluorescence resonance energy transfer (FRET) was determined. A typical FRET image observed upon stimulation with 5 μM Ca^{2+} ionophore A23187 is shown in Figure 1A. Fluorescence intensity of eNOS–cyan fluorescent protein (CFP; donor) decreased, whereas Cav-1–yellow fluorescent protein (YFP; acceptor) increased in the region of interest (ROI; white box), indicating increased FRET from eNOS to Cav-1 was induced by increased intracellular Ca^{2+} (Figure 1A). After the cells were treated with 5 μM A23187, we observed Cav-1–eNOS FRET that peaked 1.5 min after stimulation and remained elevated for 5 min (Figure 1B). Following thrombin (4 U/ml) treatment, Cav-1–eNOS FRET was also increased at 5 min (Figure 1B). Immunoprecipitation experiments showed that Cav-1–YFP binding to eNOS–CFP increased 10-fold 1 min after addition of A23187 and 5-fold 1 min after stimulation with thrombin compared with medium alone (Figure 1, C and D). To ensure that the expressed fluorescent Cav-1 and eNOS proteins were functional, CHO cells stably expressing Cav-1–YFP and eNOS–CFP were stimulated with A23187 or thrombin, and Western blotting was used to assess the phosphorylation state of Cav-1 and eNOS (Figure 1, E–G). Thus Cav-1 and eNOS phosphorylation increased in parallel with the increase in immunoprecipitation (coIP).

**Cav-1/eNOS interaction in mouse lung treated with A23187**

To assess the in vivo reality of the foregoing observations, we investigated eNOS and Cav-1 interaction in intact vessels of isolated mouse lungs perfused with 5 μM A23187 via pulmonary artery cannula. The whole-lung homogenates were prepared and immunoprecipitated with anti–Cav-1 antibody and probed for both Cav-1 and eNOS (Figure 2A). eNOS binding to Cav-1 increased sixfold upon stimulation with A23187 or thrombin, and Western blotting was used to assess the phosphorylation state of Cav-1 and eNOS activity (Michel et al., 1997a, 1997b). In contrast, eNOS translocation to internal membranes and CaM dissociation were proposed to participate in the mechanism of eNOS inhibition (Dudzinski and Michel, 2007).

Dudzinski and Michel (2007) proposed that eNOS is negatively regulated by posttranslational lipid modification. Quiiescent eNOS is anchored to the caveolar membrane by myristoylation, and thus upon stimulus-dependent activation, Cav-1 binding may be displaced by Ca^{2+}–CaM, enabling eNOS activation. eNOS is then believed to translocate from caveolae to internal membranes, where CaM dissociates, allowing for eNOS reassociation with Cav-1. Müller-Esterl's lab and also Barrett and coworkers proposed that following activation, eNOS translocation back to caveolae results in eNOS inactivation (Oess et al., 2006; Wang et al., 2009). Both of these mechanisms predict that eNOS binding to Cav-1 leads to eNOS inhibition. However, the molecular mechanisms responsible for restoring eNOS enzymatic activity to its basal state and whether its binding to Cav-1 is important in this process have not been established. In the present study, we tested the hypothesis that in endothelial cells, there is an intrinsic NO-dependent mechanism of eNOS negative feedback regulation dependent on phospho–Cav-1 binding.
action required eNOS and Cav-1 phosphorylation. HUVECs were lysed and prepared for IP by anti-p-Ser-1177 eNOS antibody (Figure 3C) under the same conditions as described earlier (Figure 3, A and B). p-Ser-1177-eNOS phosphorylation increased following ionophore stimulation, and the amount of p-Tyr-14-Cav-1 (relative to the amount of total Cav-1) that coimmunoprecipitated with p-Ser-1177-eNOS also increased fivefold relative to vehicle-treated control cells (Figure 3D).

We next determined the effect of eNOS inhibitor l-N^6-nitroarginine methyl ester (hydrochloride) (l-N^6-NAME) and Src kinase inhibitor 4-amino-5-(4-chlorophenyl)-7-((t-buty) pyrazolo [3, 4-d] pyrimidine (PP2) on the A23187-induced eNOS/Cav-1 interaction. Confluent HUVEC cultures were pretreated with medium alone, 1 mM l-N^6-NAME, or 15 μM PP2 for 30 min at 37°C, and then 5 μM A23187 was added to cells and incubated for another 5 min. eNOS, Src, and Cav-1 phosphorylation increased significantly to 4.4-, 1.3-, and 2.6-fold of vehicle-treated cells (1.0 relative unit [R.U.], respectively (Figure 3E). Pretreatment with l-N^6-NAME significantly decreased ionomophore-induced increase in Src p-Tyr-418 by 51% (from 0.337 ± 0.067 to 0.164 ± 0.094 R.U. above vehicle-treated cells; p < 0.05; n = 9) and p-Tyr-14-Cav-1 by 68%, whereas PP2 prevented A23187-induced phosphorylation of Src and Cav-1. eNOS–Ser-1177 phosphorylation induced by A23187 was not significantly affected by either PP2 or l-N^6-NAME. CoIP experiments showed that eNOS binding to Cav-1 increased eightfold after 5 min treatment with 5 μM A23187 compared with medium alone, and, of interest, both l-N^6-NAME and PP2 significantly reduced the interaction between eNOS and Cav-1 (Figure 3F). Thus, PP2 inhibition of Src activity and Cav-1 phosphorylation, as well as l-N^6-NAME inhibition of eNOS activity, significantly blocked Ca^2+–induced eNOS/Cav-1 binding in endothelial cells.

In additional studies, we assessed the role of various kinases, including Akt, PKA, AMPK, and CaMKII, in the mechanism of eNOS phosphorylation/activation in HUVECs stimulated with Ca^2+–ionophore A23187 (Supplemental Figure S4). On stimulation, p-eNOS (Ser-1177) and p-Cav-1 (Tyr-14) peaked within 3–5 min, whereas pAkt–Thr-308 was maximal at 20 min and Akt–pSer-473 was maximal at 60 min (Supplemental Figure S4, A–E). Thus eNOS activation occurred at a faster rate than Akt activation, leading us to conclude that Akt does not play a significant role in the early phase of Ca^2+–induced eNOS activation. Furthermore, we assessed eNOS–Ser-1177 phosphorylation induced by A23187 following 30 min of pretreatment of cells with 10 μM H89 (PKA inhibitor), 30 μM 5-iodo-tubercidin (AMPK inhibitor), or 10 μM STO-609 (CaMKII inhibitor). We observed that only the CaMKII inhibitor STO-609 significantly blocked Ca^2+–induced eNOS–Ser-1177 phosphorylation by 50% (Supplemental Figure S4, F and G).

**p-Tyr-14-Cav-1 promotes eNOS binding and decreases eNOS activity**

To further clarify the role of Cav-1 versus eNOS phosphorylation in enhanced binding of eNOS to Cav-1, we coexpressed either Cav-1 and eNOS phosphorylation induces Cav-1/eNOS interaction

Stimulation of human umbilical vascular endothelial cells (HUVECs) with 5 μM A23187, 4 U/ml thrombin, or 20 ng/ml vascular endothelial growth factor (VEGF) increased eNOS activity, as measured by 4,5-diaminofluorescein-2 diacetate (DAF-2 DA) fluorescence intensity, by 7.2–, 6.5–, and 4.6-fold, respectively, over untreated HUVECs (Supplemental Figure S1A). NO release was maximal 1 min after addition of 5 μM A23187, returning toward prestimulation levels by 7.2-, 6.5-, and 4.6-fold, respectively, over untreated HUVECs (3E). Pretreatment of cells with 10 μM H89 (PKA inhibitor), 30 μM 5-iodo-tubercidin (AMPK inhibitor), or 10 μM STO-609 (CaMKII inhibitor). We observed that only the CaMKII inhibitor STO-609 significantly blocked Ca^2+–induced eNOS/Cav-1 binding in endothelial cells.

In additional studies, we assessed the role of various kinases, including Akt, PKA, AMPK, and CaMKII, in the mechanism of eNOS phosphorylation/activation in HUVECs stimulated with Ca^2+–ionophore A23187 (Supplemental Figure S4). On stimulation, p-eNOS (Ser-1177) and p-Cav-1 (Tyr-14) peaked within 3–5 min, whereas pAkt–Thr-308 was maximal at 20 min and Akt–pSer-473 was maximal at 60 min (Supplemental Figure S4, A–E). Thus eNOS activation occurred at a faster rate than Akt activation, leading us to conclude that Akt does not play a significant role in the early phase of Ca^2+–induced eNOS activation. Furthermore, we assessed eNOS–Ser-1177 phosphorylation induced by A23187 following 30 min of pretreatment of cells with 10 μM H89 (PKA inhibitor), 30 μM 5-iodo-tubercidin (AMPK inhibitor), or 10 μM STO-609 (CaMKII inhibitor). We observed that only the CaMKII inhibitor STO-609 significantly blocked Ca^2+–induced eNOS–Ser-1177 phosphorylation by 50% (Supplemental Figure S4, F and G).
These experiments involved the transient transfection of WT-eNOS-CFP, eNOS-S1177D-CFP, and eNOS-S1177A-CFP in HEK cells stably expressing WT-Cav-1-YFP, Y14D-Cav-1-YFP, or Y14F-Cav-1-YFP. Cells were lysed 48 h after transfection and immunoprecipitated with anti-Cav-1 antibody. Both eNOS and Cav-1 were measured by Western blot after IP (Figure 4A), and the data from three separate experiments were averaged as shown in the bar graph. We observed Y14D-Cav-1 binding to either WT-eNOS or S1177D-eNOS to be equivalent but 4.2-fold greater than the binding of WT-eNOS and WT-Cav-1, indicating that Cav-1 phosphorylation is an important determinant of eNOS binding. Moreover, binding of the phosphodefective S1177A-eNOS mutant to WT- or Y14D-Cav-1 was significantly reduced, suggesting eNOS phosphorylation is also an important determinant of the binding reaction. Y14F-Cav-1 showed much lower binding to all eNOS constructs compared with WT- or Y14D-Cav-1, suggesting the phospho-defective Cav-1 conformation does not bind well to eNOS (Figure 4A).

The level of protein expression achieved with each Cav-1 and eNOS construct before IP was similar, as shown in Figure 4B, and coIP of untagged proteins yielded similar results.

We next determined whether enhanced eNOS binding to p-Tyr-14-Cav-1 affects eNOS activity. Nitrite (NO$_2^-$, the stable product of NO autoxidation) concentration was measured in media from HEK cells stably expressing WT-eNOS (Supplemental Figure S5) following transient transfection with WT-Cav-1-YFP, Y14D-Cav-1-YFP, and Y14F-Cav-1-YFP as before. Cells were then treated with 5 μM A23187 for 30 min. Compared to HEK/eNOS cells, cells transfected with WT-Cav-1-YFP showed 31% less NO production (1.00 ± 0.021 vs. 0.693 ± 0.029 R.U.; p < 0.001; n = 8). Furthermore, accumulated NO$_2^-$ in cell culture media was 40% less in HEK/eNOS cells transfected with Y14D-Cav-1 mutant than in WT-Cav-1–expressing cells (Figure 4C). To determine the effect of Y14D-Cav-1 on eNOS activity, NO$_2^-$ production per minute per 10^6 HEK/eNOS cells transfected with WT-Cav-1-YFP, Y14D-Cav-1-YFP, and Y14F-Cav-1-YFP as before. Cells were then treated with 5 μM A23187 for 30 min. Compared to HEK/eNOS cells, cells transfected with WT-Cav-1-YFP showed 31% less NO production (1.00 ± 0.021 vs. 0.693 ± 0.029 R.U.; p < 0.001; n = 8). Furthermore, accumulated NO$_2^-$ in cell culture media was 40% less in HEK/eNOS cells transfected with Y14D-Cav-1 mutant than in WT-Cav-1–expressing cells (Figure 4C). To determine the effect of Y14D-Cav-1 on eNOS activity, NO$_2^-$ production per minute per 10^6 HEK/eNOS cells transfected with WT-Cav-1-YFP, Y14D-Cav-1-YFP, and Y14F-Cav-1-YFP mutants was calculated from serial samples. A23187-induced eNOS activation was maximal after 1 min, returned to near basal activity at 3 min, and then remained low at all later time points (Figure 4D), which was similar to the time course of NO generation observed in HUVECs (Supplemental Figure S1B). Importantly, these data indicate that Y14D-Cav-1 limits A23187-stimulated eNOS activation compared with cells expressing an equivalent level of WT-Cav-1 or phosphodefective Y14F-Cav-1.

![Figure 3](image-url)
times indicated (Figure 5A). eNOS protein expression was significantly reduced after eNOS siRNA treatment. In addition, the basal p-Tyr-418-Src level was reduced by 50% in eNOS-depleted cells and remained low up to 10 min after addition of A23187 compared with scrambled siRNA-treated cells (Figure 5A). Thus, p-Src was significantly lower at each time point in eNOS siRNA-treated HUVECs compared with scrambled siRNA-treated HUVECs, suggesting that NO production by eNOS in response to Ca\(^{2+}\) increases Src activity. We speculate that residual Src activation may be due to nNOS-derived NO (Bachetti et al., 2004).

Consistent with this finding, p-Tyr-14-Cav-1 induced by A23187 stimulation was also significantly reduced in HUVECs treated with eNOS siRNA (Figure 5A). Thus eNOS and NO production lie upstream of Src activation and Cav-1 phosphorylation. In other experiments, Cav-1–null mouse embryonic fibroblasts (MEFs) were stimulated with 0.2 mM DEA NONOate, an NO donor, and lysates were probed for p-Tyr-418-Src. As shown in Figure 5B, NO donor increased Src activity by 80% compared with nontreated cells, in accord with the finding that eNOS expression is an important determinant of Src activation. In WT MEFs stimulated with DEA-NONOate, we observed a 50% increase in pTyr-418-Src, and thus 37% less Src activation than observed in WT MEFs, consistent with the idea that phosphor–Cav-1 plays an important role in the mechanism of Src inactivation (Cao et al., 2002; Place et al., 2011).

To further address the role of NO signaling in the mechanism of Src activation, WT-HEK cells and HEK cells stably expressing eNOS were stimulated with A23187. As shown by Western blotting, we observed a 66% increase in Src-Tyr-418 phosphorylation in eNOS-expressing HEK cells treated for 5 min with A23187 compared with WT-HEK cells lacking eNOS (Figure 5C; n = 7, p < 0.001). NO activation of Src was also determined using a Src FRET biosensor (Figure 5D), which is composed of CFP, the Src SH2 domain, a flexible linker, a Src substrate peptide, and YFP (Wang et al., 2005). On Src activation, CFP moves away from YFP and FRET decreases. eNOS-expressing HEK cells transiently transfected with the biosensor were imaged by confocal microscopy (a typical FRET image is shown in Figure 5D). After stimulation with 5 μM A23187, CFP intensity increased, whereas as that of YFP decreased, indicating CFP movement away from YFP and thus evidence of increased Src kinase activity. Src kinase activity indicated by FRET was blocked by l-NAME and PP2 (Figure 5E). As a negative control,
Proposed mechanism of NO-dependent negative feedback inhibition of eNOS

Data shown here indicate that stimulation of endothelial cells with calcium ionophore A23187, thrombin, or VEGF induces eNOS activation and NO-dependent Src activation. We also observed Cav-1 phosphorylation and enhanced binding between phospho-Cav-1 and eNOS, which was associated with a decrease in eNOS activity. Thus, as summarized in Figure 6, we propose a mechanism in which phospho-Cav-1 binding to eNOS decreases eNOS activity. The proposed negative feedback mechanism is supported by experimental data that show that eNOS–Cav-1 interactions (colip and FRET) are blocked by eNOS inhibitor l-NAME and Src inhibitor PP2 and that phosphomimicking mutants rather than phosphodefective Cav-1 and eNOS mutants specifically bind to each other. NO and Src-dependent phosphorylation of Cav-1 therefore may be a primary mechanism of eNOS negative feedback regulation in endothelial cells.

DISCUSSION

Here we demonstrate a novel phospho-Cav-1–dependent mechanism of eNOS/Cav-1 binding that mediates eNOS inactivation. eNOS-derived NO production increased Src activity and subsequently the phosphorylation of Cav-1 Tyr-14 in endothelial cells, which promoted the binding of eNOS and Cav-1. Thus these data suggest NO production per se negatively regulates eNOS activity secondary to Cav-1 Tyr-14 phosphorylation. The association between eNOS and Cav-1, as assessed by coIP of endogenous and expressed proteins, was enhanced by Cav-1 Tyr-14 phosphorylation and phosphomimicking Y14D Cav-1 mutant and blocked by l-NAME, Src inhibitor PP2, and Y14F phosphodefective mutant. FRET analysis of Cav1-YFP and eNOS-CFP, together with measures of Ca²⁺-induced NO production, support the hypothesis that p-Tyr-14-Cav-1 provides a favorable conformation for CSD-dependent binding of phosphorylated eNOS, resulting in inhibition of eNOS activity. Of interest, in additional studies we observed that depletion of Cav-1 from human endothelial cells with siRNA enhanced Ca²⁺-induced eNOS activation (unpublished data). However, we also noted decreased eNOS protein level in Cav-1 siRNA-treated cells, suggesting that Cav-1 may stabilize eNOS and prevent degradation. The mechanism by which Cav-1 serves to regulate eNOS expression/stability and whether Cav-1 phosphorylation also plays a role in this process require further investigation.
NO is a well-established signaling molecule and key regulator of cardiovascular function (Furchgott and Zawadzki, 1980; Huang et al., 1995). Tight control of NO production is believed to be critically important for maintenance of cellular and tissue homeostasis. The importance of Cav-1, the primary coat protein of caveolae, in the regulation of eNOS activity and NO production has been studied in recent years. eNOS localized to the inner leaflet of caveolar membranes and in the Golgi in endothelial cells is believed to be held in an inactive state due to direct interaction with Cav-1 (Frank et al., 2003; Gratton et al., 2004). The binding of eNOS to Cav-1 maintains eNOS in its inactive conformation, whereas CaM binding increases eNOS activity (Michel et al., 1997a, 1997b; Gratton et al., 2004; Ju et al., 1997). eNOS contains a consensus caveolin-binding motif located within amino acids 348–356 (García-Cardeña et al., 1997; Smart et al., 1999; Couet et al., 1997), and Cav-1 overexpression in COS-7 cells decreases eNOS activity (García-Cardeña et al., 1997), consistent with the essential role of Cav-1 in restraining eNOS activity. Several studies have also shown increased NO production in Cav-1−/− mice and that disruption of the eNOS–Cav-1 complex leads to increased eNOS activity and prolonged NO release, which has been linked to tissue and organ pathologies (Drab et al., 2001; Zhao et al., 2002; Wunderlich et al., 2006; Maniatis et al., 2008; Razani et al., 2001). Whether Cav-1 plays a role specifically in the mechanism of eNOS inactivation has not been established.

We addressed the mechanism regulating interaction of eNOS with Cav-1 following Ca2+-, VEGF-, and thrombin-induced eNOS activation. Cells were treated with agonists to stimulate a rise in intracellular Ca2+ concentration, which was shown to induce eNOS activation and production of NO (Jin, 2006). We observed Src kinase activation downstream of NO generation, which has been ascribed to S-nitrosylation of Src at Cys-498 (Raman et al., 1998). The resultant phosphorylation of eNOS Ser-1177 and Cav-1 Tyr-14 increased eNOS/Cav-1 binding, which was associated with a decrease in eNOS activity. This was evident from results showing that WT-Cav-1 interacted equally well with WT-eNOS and with phosphomimicking or phosphodefective eNOS mutants expressed in HEK cells, whereas the phosphomimicking Cav-1 mutant (Cav-1-Y14D) interacted strongly with WT-eNOS and phosphomimicking eNOS but not with phosphodefective eNOS. In contrast, phosphodefective Cav-1 mutant (Cav-1-Y14F) failed to interact with any of the eNOS variants. The results of these phosphomimicking and phosphodefective Cav-1 and eNOS mutant–binding studies, even with the potential caveat that these mutants simply mimic the presence or absence of the negatively charged phosphate residue, are consistent with that observed with endogenous proteins in the absence and presence of Src kinase inhibitor. Our conclusion from these studies is that Cav-1 phosphorylation at Tyr-14 provides the most favorable conformation for eNOS binding and inhibition of eNOS activity.

Ca2+-calmodulin activates eNOS, and high concentration of CaM (1 μM) can prevent eNOS/Cav-1 binding in vitro (Barnetchez et al., 2011). In the present studies, we observed stimulation- and time-dependent increase in CaM coIP with eNOS following addition of Ca2+-ionophore A23187 (Supplemental Figure S3). In this same experiment we observed an increase in the amount of Cav-1 that coimmunoprecipitated with eNOS. Data in the literature demonstrate inhibition of eNOS-derived NO production by Cav-1 or Cav-1 scaffold domain peptide that can be completely reversed by CaM (Ghosh et al., 1998). However, it has not been shown to our knowledge that CaM binding to eNOS promotes release of Cav-1 from eNOS. Similarly, whereas addition of Cav-1 or Cav-CSD decreases eNOS activity, CaM was not shown to be displaced from eNOS (Raman et al., 1998). Thus, since eNOS has separate binding sites for CaM (amino acids [aa] 491–510; Michel et al., 1997b) and Cav-1 (aa 348–356; Couet et al., 1997), data presented here indicate that activation of CaM and phosphorylation of Cav-1 increase their binding to eNOS. In both cases, the binding of either CaM or Cav-1 to eNOS is believed to induce a conformational change in the eNOS home-domain activation motif (aa 96–101, Raman et al., 1998).

A distinct feature of these studies was that we monitored interactions between eNOS and Cav-1 by both FRET and coIP. For the latter, we used the total membrane fraction (containing virtually 100% of the total eNOS and Cav-1 protein) instead of membrane-enriched fractions that contain only a small amount of the total eNOS (Supplemental Figure S2). Of interest, coIP of endogenous eNOS and Cav-1 from HUVEC total cell lysates increased upon Ca2+-dependent stimulation, peaking ∼5 min after treatment with A23187. In transfected CHO cells, eNOS–Cav-1 binding also increased upon stimulation with A23187 or thrombin, as shown by coIP and FRET. Similarly, we observed increased interaction between eNOS and Cav-1 in mouse lungs, indicating the physiological relevance of the cell observations describing the basis of the interaction of eNOS with phospho–Cav-1.

A key question that arose from our studies relates to the mechanism of NO-induced Src activation and thereby Cav-1 phosphorylation on Tyr-14. In HUVECs in which eNOS was depleted by siRNA treatment, we observed significantly reduced phosphorylation of Src and Cav-1 in response to A23187, in contrast to control cells. It is possible that nNOS may be responsible for residual Src activation observed in eNOS siRNA or l-NNAME–treated cells, as this isoform is also expressed in endothelial cells and believed to account for up to 20% of Ca2+-induced NO release (Bachetti et al., 2004). Furthermore, Src FRET biosensor experiments showed that phosphorylation and activation of eNOS by addition of A23187 stimulated Src activity, which was inhibited by the pharmacological Src inhibitor PP2, as well as by eNOS inhibitor l-NNAME. Moreover, NO derived from an exogenous source, DEA NONOate, induced Src activation, consistent with previous reports (Akhand et al., 1999; Monteiro et al., 2000) and evidence that NO-mediated S-nitrosylation of Sry Cys-498 increases Src kinase activity (increase in Src p-Tyr-418) in a dose-dependent manner (Raman et al., 1998). It should be noted...
here that phosphorylated Cav-1 also functions as a negative regulator of Src activity by facilitating the recruitment of C-terminal Src kinase (Csk), which is known to phosphorylate Src-negative regulatory Tyr-529 and induce Src inactivation (Place et al., 2011).

The functional significance of Cav-1 Tyr-14 phosphorylation was previously linked to tumor cell migration (Joshi et al., 2008), modulation of focal adhesion (Grande-García et al., 2007), mechanotransduction (Radel et al., 2007), and caveolae formation and endocytosis (Minshall et al., 2000; Shajahan et al., 2004; Orlichenko et al., 2006; Hu et al., 2006, 2008; Sverdlow et al., 2007, 2009; Sun et al., 2009). Data presented here indicate that pTyr-14-Cav-1 may obtain a favorable conformation that leads to enhanced docking of proteins, presumably via the CSD, thus enabling recruitment of proteins to caveolae, where signaling can be regulated. We posit that a negative feedback mechanism that returns eNOS activity to its ground state may be pathophysiologically important in vascular inflammation, which is often associated with dysregulated eNOS activity, persistent NO production, and NO modification of endothelial regulatory proteins (Siddiqui et al., 2011).

**MATERIALS AND METHODS**

**Cell culture and transfection**

HUVECs were purchased from Vec Technologies (Rensselaer, NY). Cav-1-null and WT mouse embryonic fibroblasts, HEK 293, and CHO-K1 cells were from the American Type Culture Collection (Rockville, MD). HUVEC growth medium (EGM-2 plus Bullet kit) was from Lonza (Walkersville, MD). Nitrocellulose membrane was from Bio-Rad Laboratories (Hercules, CA). Supersignal West Femto was from ThermoFisher Scientific (Rockford, IL). HAM's F-12 (for CHO cells) and DMEM (for HEK 293 cells and HUVECs) were purchased from Vec Technologies (Rensselaer, NY). Cav-1–null and WT mouse embryonic fibroblasts, HEK 293, and HUVECs were purchased from Vec Technologies (Rensselaer, NY). Recombinant human IL-1β, IL-6, TNF, IL. siRNA of eNOS and transfection reagent DharmaFect 1 were from Dharmacon (Lafayette, CO). DAPI, Lipofectamine 2000, and growth of single cells in 96-well plates in presence of Geneticin. lines were obtained by fluorescence-activated cell sorting plating at passages 5–7. For immunofluorescence microscopy, cells were for NO measurement was from Corning (Corning, NY).

**Reagents**

Reagents were from Dharmacon (Lafayette, CO). DAPI, Lipofectamine 2000, 4,5-DAF-2 DA, 5-iodotubercidin, and thionin were from Sigma-Aldrich (St. Louis, MO). Human α-thrombin was from Enzyme Research Laboratories (South Bend, IN). 4,5-DAF-2 DA, 5-iodotubercidin, and STO-609 were from Calbiochem (La Jolla, CA). Recombinant human actinomycin D, 5-iodotubercidin, and thionin were from Sigma-Aldrich (St. Louis, MO). Human α-thrombin was from Enzyme Research Laboratories (South Bend, IN). 4,5-DAF-2 DA, 5-iodotubercidin, and thionin were from Sigma-Aldrich (St. Louis, MO).

**Construction of Cav-1-YFP, Cav-1-Y14D-YFP, and Cav1-Y14F-YFP plasmids**

To generate the wild-type, C-terminal, YFP-tagged caveolin-1 (Cav-1-YFP), full-length Homo sapiens Cav-1 was used as a template in a PCR with DNA Phusion High-Fidelity Polymerase (New England BioLabs, Ipswich, MA), using the following primer pair lacking the stop codon: Cav1-WT-F: 5′-ACTAGCTAG CGACGCGCATGTCTGGGGGCAAAT-AC-3′ and Cav1-WT-R: 5′-ACTGGATCCATTTTC-TTCTTGAAGTTGATGCG-3′. The resulting PCR fragment was digested with restriction enzymes 5′-NheI and 3′-KpnI (italicized in the primers) and subcloned into pEYFP-N1 vector (Clontech, Mountain View, CA).

To generate the Cav-1-Y14D-YFP plasmid, a two-step PCR method was used. In the first step, two PCR fragments were generated using the wild-type caveolin 1 cDNA as the DNA template and the following primer pairs: fragment A, primer pairs Cav1-WT-F and Cav1-Y14D-R-5′-ATGGGACAGGTGTGAGATGCC-3′, and fragment B, primer pairs Cav1-Y14D-R-5′-ATGGGACAGGTGTGAGATGCC-3′ and Cav1-WT-R. As shown in the primers, the underlined base pair resulted in Y144-to-D14 mutation. In the second step, a final PCR product, fragment C, was generated by combining fragments A and B together as PCR DNA templates with primer pair Cav1-WT-F and Cav1-WT-R. The fragment C was digested with NheI and KpnI ligated at the same restriction sites of pEYFP-N1 vector.

To generate the Cav1-Y14F-YFP plasmid, the Cav1-WT-F and Cav1-Y14F-R-5′-ATGGGACAGGTGTGAGATGCC-3′ primer pairs were used. In the first step, two PCR fragments were generated using the Cav1-WT-F and Cav1-Y14F-R-5′-ATGGGACAGGTGTGAGATGCC-3′ primer pairs as DNA templates. As shown in the primers, the underlined base pair resulted in Y144-to-F14 mutation. In the second step, a final PCR product, fragment C, was generated by combining fragments A and B together as PCR DNA templates with primer pair Cav1-WT-F and Cav1-WT-R. The fragment C was digested with NheI and KpnI ligated at the same restriction sites of pEYFP-N1 vector.

**Construction of pcDNA3-eNOS-CFP, pcDNA3-eNOS-S1177D-CFP, and pcDNA3-eNOS-S1177A-CFP plasmids**

The 5′-NheI/3′-SmaI fragment of CFP from pECPF-C1 (Clontech) was subcloned into pACGp67A (BD Biosciences) at the C-terminus, full-length Homo sapiens eNOS cDNA (with GenBank Accession number NM_000603 from OriGene Technologies, Rockville, MD) was used as DNA template in a PCR to generate eNOS PCR fragment that contained Agel at both 5′ and 3′ ends. The 5′-3′-Agel fragment of eNOS was then digested and ligated to the same restriction sites on the pcDNA3-CFP vector to create the pcDNA3-eNOS-CFP plasmid. The primers used were eNOS-Agel-F, eNOS-Agel-R, eNOS-Agel-F, and eNOS-Agel-R.
Fluorescence resonance energy transfer et al. Analyzer (Sievers Instruments, Boulder, CO). NO release from trans-accumulation as described (Bonini concentration in the culture media was assessed by measuring NO Arg (HBSS plus 0.2–0.5 mM HUVECs were washed twice with HBSS and incubated with HBSS-Chemiluminescence-based NO measurements repeated at least three times, and eight wells were used in each (Molecular Devices, Sunnyvale, CA). DAF-2 DA experiments were length, 538 nm) was measured temporally at 37°C from 0 to 60 min phore A23187, thrombin, VEGF, or KRP buffer was added to the absence or presence of 1 mM KRP buffer, and then incubated with KRP buffer for 30 min at room temperature, washed again with the cells lysates in 1.5-ml Eppendorf tubes and rotated overnight at 4°C and then rotated for 2 h at 4°C with protein A beads. The beads were washed five times with Tris buffer containing 1% ODG. The proteins were eluted with Laemml buffer, subjected to SDS-PAGE, transferred to nitrocellulose membranes, and probed with primary and secondary antibodies. Membrane-bound antibodies were visualized using Supersignal West Femto Kit.

Immunoprecipitation and Western blotting After treatment with different reagents, cells were lysed by sonication in 2% ODG in Tris buffer (pH 7.50, 50 mM Tris, 150 mM NaCl, 1 mM NaF, 1 mM EDTA, 1 mM Na3VO4, 44 μg/ml phenylmethylsulfonyl fluoride [PMSF], 1% protease inhibitor cocktail). The lysates were centrifuged for 20 min at 16,000 × g at 4°C. Supernatants were collected for IP or Western blot analysis. For IP, antibodies were added to the cell lysates in 1.5-ml Eppendorf tubes and rotated overnight at 4°C. After serum deprivation in culture medium containing 0.5% FBS overnight or 0.1% FBS for 5–7 h, cells were washed three times with serum-free medium. Agonists were added to the cells at indicated times and incubated at 37°C. For inhibitor experiments, inhibitors were added 30 min prior to stimulation. Finally, after washing once with ice-cold Tris buffer (50 mM Tris, 150 mM NaCl, 1 mM NaF, 1 mM EDTA, 1 mM Na3VO4, 44 μg/ml PMSF, pH 7.50), the cells were collected and lysed for Western blotting or IP.

Phosphorylation of eNOS (Ser-1177), Src (Tyr-418), Cav-1 (Tyr-14), and Akt (Thr-308, Ser-473) after stimulation with A23187 After serum deprivation in culture medium containing 0.5% FBS overnight or 0.1% FBS for 5–7 h, cells were washed three times with serum-free medium. Agonists were added to the cells at indicated times and incubated at 37°C. After treatment with different reagents, cells were lysed by sonication in 2% ODG overnight or 0.1% FBS for 5–7 h, cells were washed three times with serum-free medium. Agonists were added to the cells at indicated times and incubated at 37°C. For inhibitor experiments, inhibitors were added 30 min prior to stimulation. Finally, after washing once with Tris buffer (50 mM Tris, 150 mM NaCl, 1 mM NaF, 1 mM EDTA, 1 mM Na3VO4, 44 μg/ml PMSF, pH 7.50), the cells were collected and lysed for Western blotting or IP.

Comparison of membrane fractions for coIP experiment in HUVECs Membrane-enriched fractions of HUVEC were prepared for coIP as described (Busconi and Michel, 1993; Feron et al., 1998), but with the following modifications. Briefly, after treatment with vehicle or 5 μM A23187 for 3 min at 37°C, cells were collected and sonicated in phosphate-buffered saline (containing 1% protease inhibitor cocktail) and centrifuged at 100,000 × g for 30 min at 4°C. The supernatants (cytosolic fraction) were collected, and pellets were dissolved in 2% ODG in Tris buffer and centrifuged again for 30 min at 100,000 × g. The supernatants (membrane-enriched fraction) were collected and the pellets were dissolved in RIPA buffer (150 mM NaCl, 1.0% IGEPAL CA-630, 0.5% sodium deoxycholate, 0.1% SDS, and 50 mM Tris, pH 8.0) by sonication. Insoluble fractions after ODG were collected for centrifugation for 10 min at 1000 × g. For isolation of the total membrane fraction, cells were dissolved in 2% ODG (Tris buffer) by sonication, and supernatants (total membrane fraction) were collected after centrifugation for 20 min at 16,000 × g. The pellets were then dissolved by sonication in RIPA buffer. Supernatants (insoluble fractions in ODG) were cleared by centrifugation for 10 min at 1000 × g, and then all fractions were prepared for immunoblotting or IP.

siRNA-mediated eNOS depletion Confluent HUVECs seeded in 35-mm wells were grown to ~40% confluence and transfected with eNOS or scrambled siRNA at a final concentration of 100 nM. After 72 h, cells were stimulated and lysed for Western blot analysis.

Molecular Biology of the Cell

Analysis of eNOS activity by DAF-2 fluorescence Intracellular NO measurement using the NO-specific fluorescence probe DAF-2 DA was described previously (Nakatsubo et al., 1998; Kojima et al., 1998). Briefly, after incubation in serum-free EGM-2 (containing 0.1% BSA) overnight, endothelial cells on 96-well plates were washed with Krebs–Ringer phosphate (KRP) buffer (120 mM NaCl, 4.8 mM KCl, 0.54 mM CaCl2, 1.2 mM MgSO4, 11 mM glucose, 15.9 mM sodium phosphate, pH 7.20), incubated with 5 μM DAF-2 DA in KRP buffer for 30 min at room temperature, washed again with KRP buffer, and then incubated with KRP buffer for 30 min at 37°C in the absence or presence of 1 mM L-NAME, after which calcium ionophore A23187, thrombin, VEGF, or KRP buffer was added to the wells. Fluorescence (emission wavelength, 485 nm; excitation wavelength, 538 nm) was measured temporally at 37°C from 0 to 60 min using the bottom-reading mode in a FlexStation II plate reader (Molecular Devices, Sunnyvale, CA). DAF-2 DA experiments were repeated at least three times, and eight wells were used in each experiment.

Chemiluminescence-based NO measurements HUVECs were washed twice with HBSS and incubated with HBSS-Arg (HBSS plus 0.2–0.5 mM L-arginine) for 30 min at 37°C. The cells were then treated with agonists for up to 30 min in HBSS-Arg. NO concentration in the culture media was assayed by measuring NO2 accumulation as described (Bonini et al., 2002), using a Sievers NO Analyzer (Sievers Instruments, Boulder, CO). NO release from transfected HEK cells was assessed from NO2 level in the media (Michel et al., 1997a; Bernatchez et al., 2005) and reported as μmol NO2/ min per 106 cells.

Fluorescence resonance energy transfer Cells cultured on glass-bottom dishes were imaged with a Zeiss LSM-510 META confocal microscope (Carl Zeiss, Jena, Germany) as described previously (Chen et al., 2006). Two images of the basal fluorescence were collected before addition of stimulus. Intensity of donor and acceptor emission was determined from selected ROIs and was averaged and plotted as acceptor/donor (YFP/CFP) as an index of Src biosensor activity (Wang et al., 2005) or donor/acceptor (CFP/YFP) to reflect temporal changes in eNOS/Cav-1 FRET.
Mouse lung preparations
Anesthetized mice were killed and lungs perfused via pulmonary artery cannula with DMEM/F-12 medium (without FBS) for 10 min at 0.2 ml/min at 37°C. Lungs were then perfused with medium containing 5 μM A23187 for 2, 3, and 10 min and then rinsed with cold medium containing phosphatase inhibitors for another 3 min. Lungs were homogenized and sonicated in Tris buffer containing 2% ODG. Lysates were centrifuged for 20 min at 16,000 × g at 4°C, and supernatants were collected for immunoblotting or IP.

Statistical analysis
Data are presented as mean ± SEM. Statistical analysis was performed by Student's t test or one-way analysis of variance using Graph InStat software (San Diego, CA).

ACKNOWLEDGMENTS
We thank Maricela Castellon for technical assistance, William Sessa for providing eNOS cDNA, and Shu Chien for providing the Src FRET biosensor cDNA. This work was supported by National Institutes of Health National Heart, Lung, and Blood Institute Grants R01 HL045638, R01 HL71626, and R01 HL60678.
